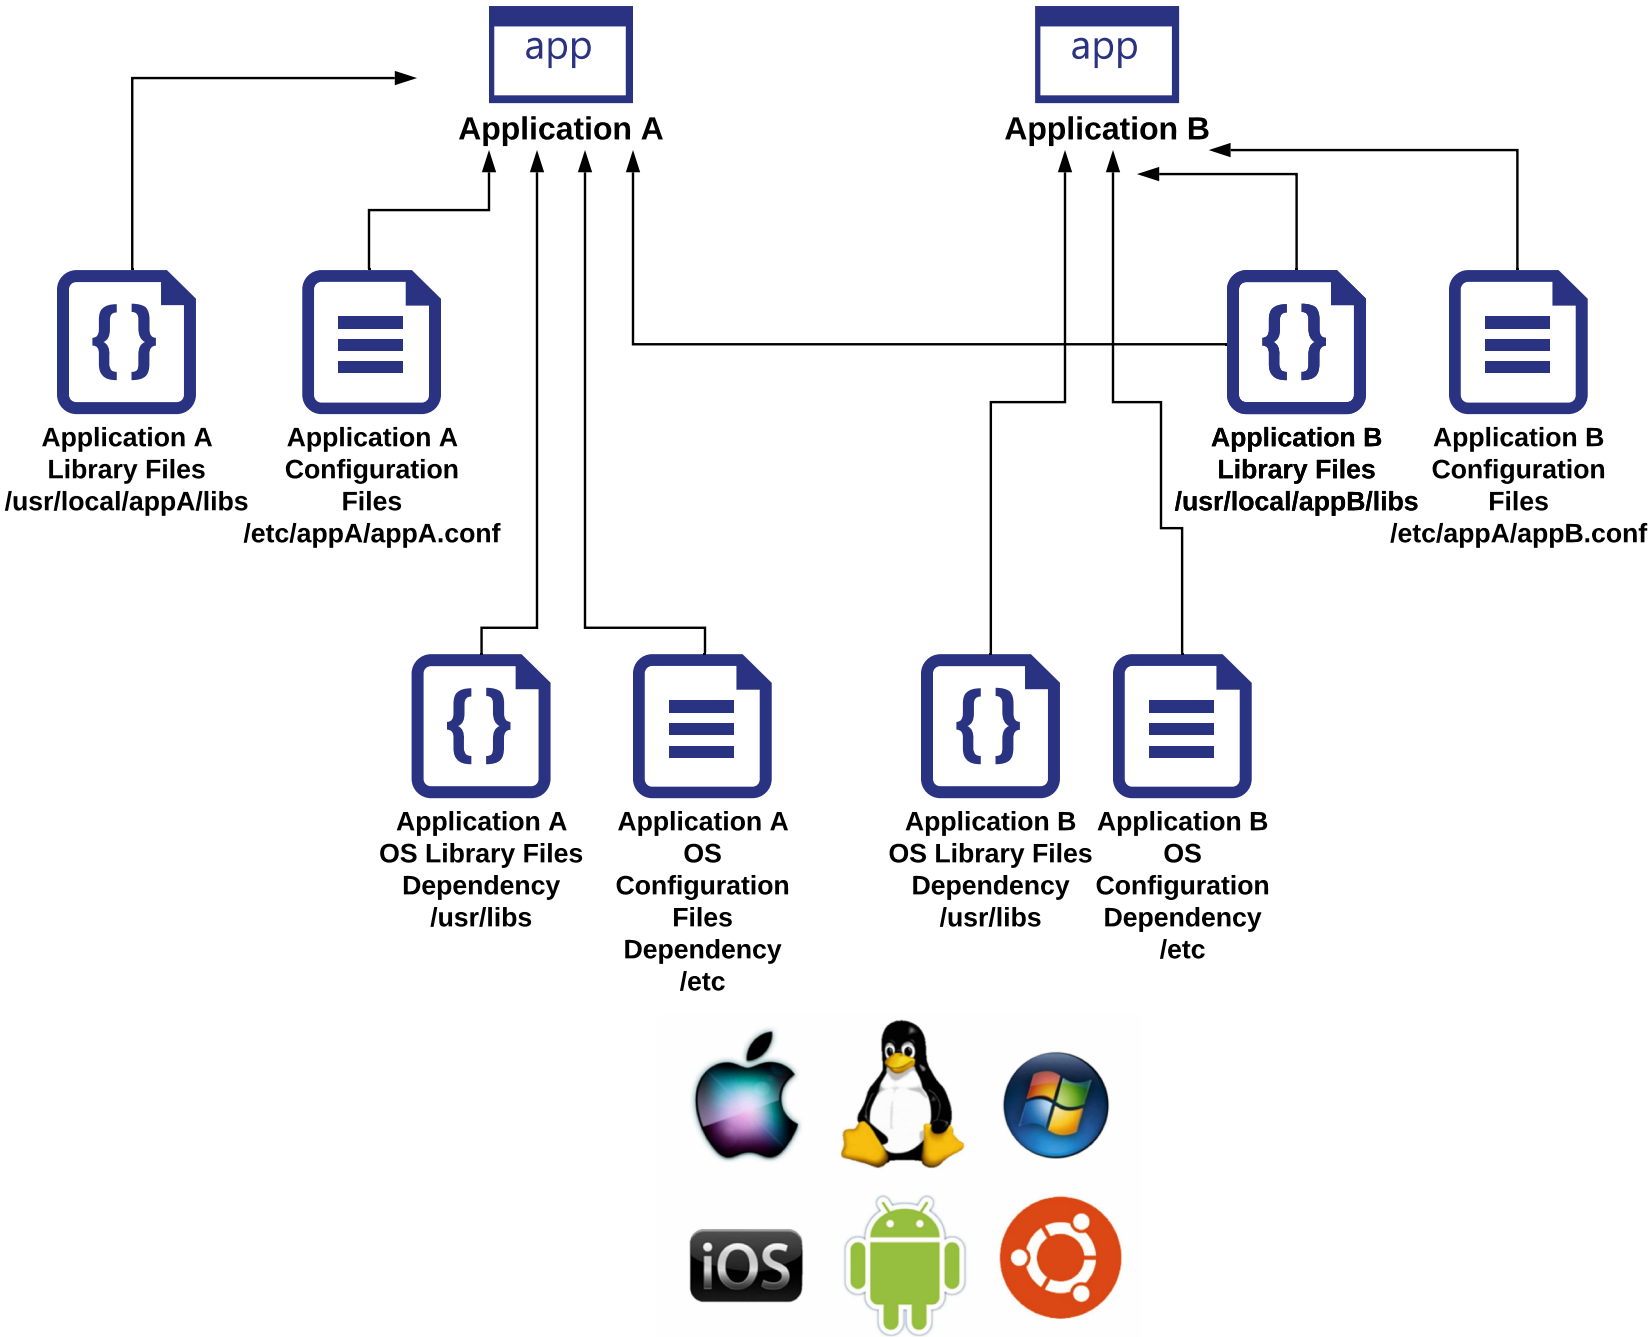
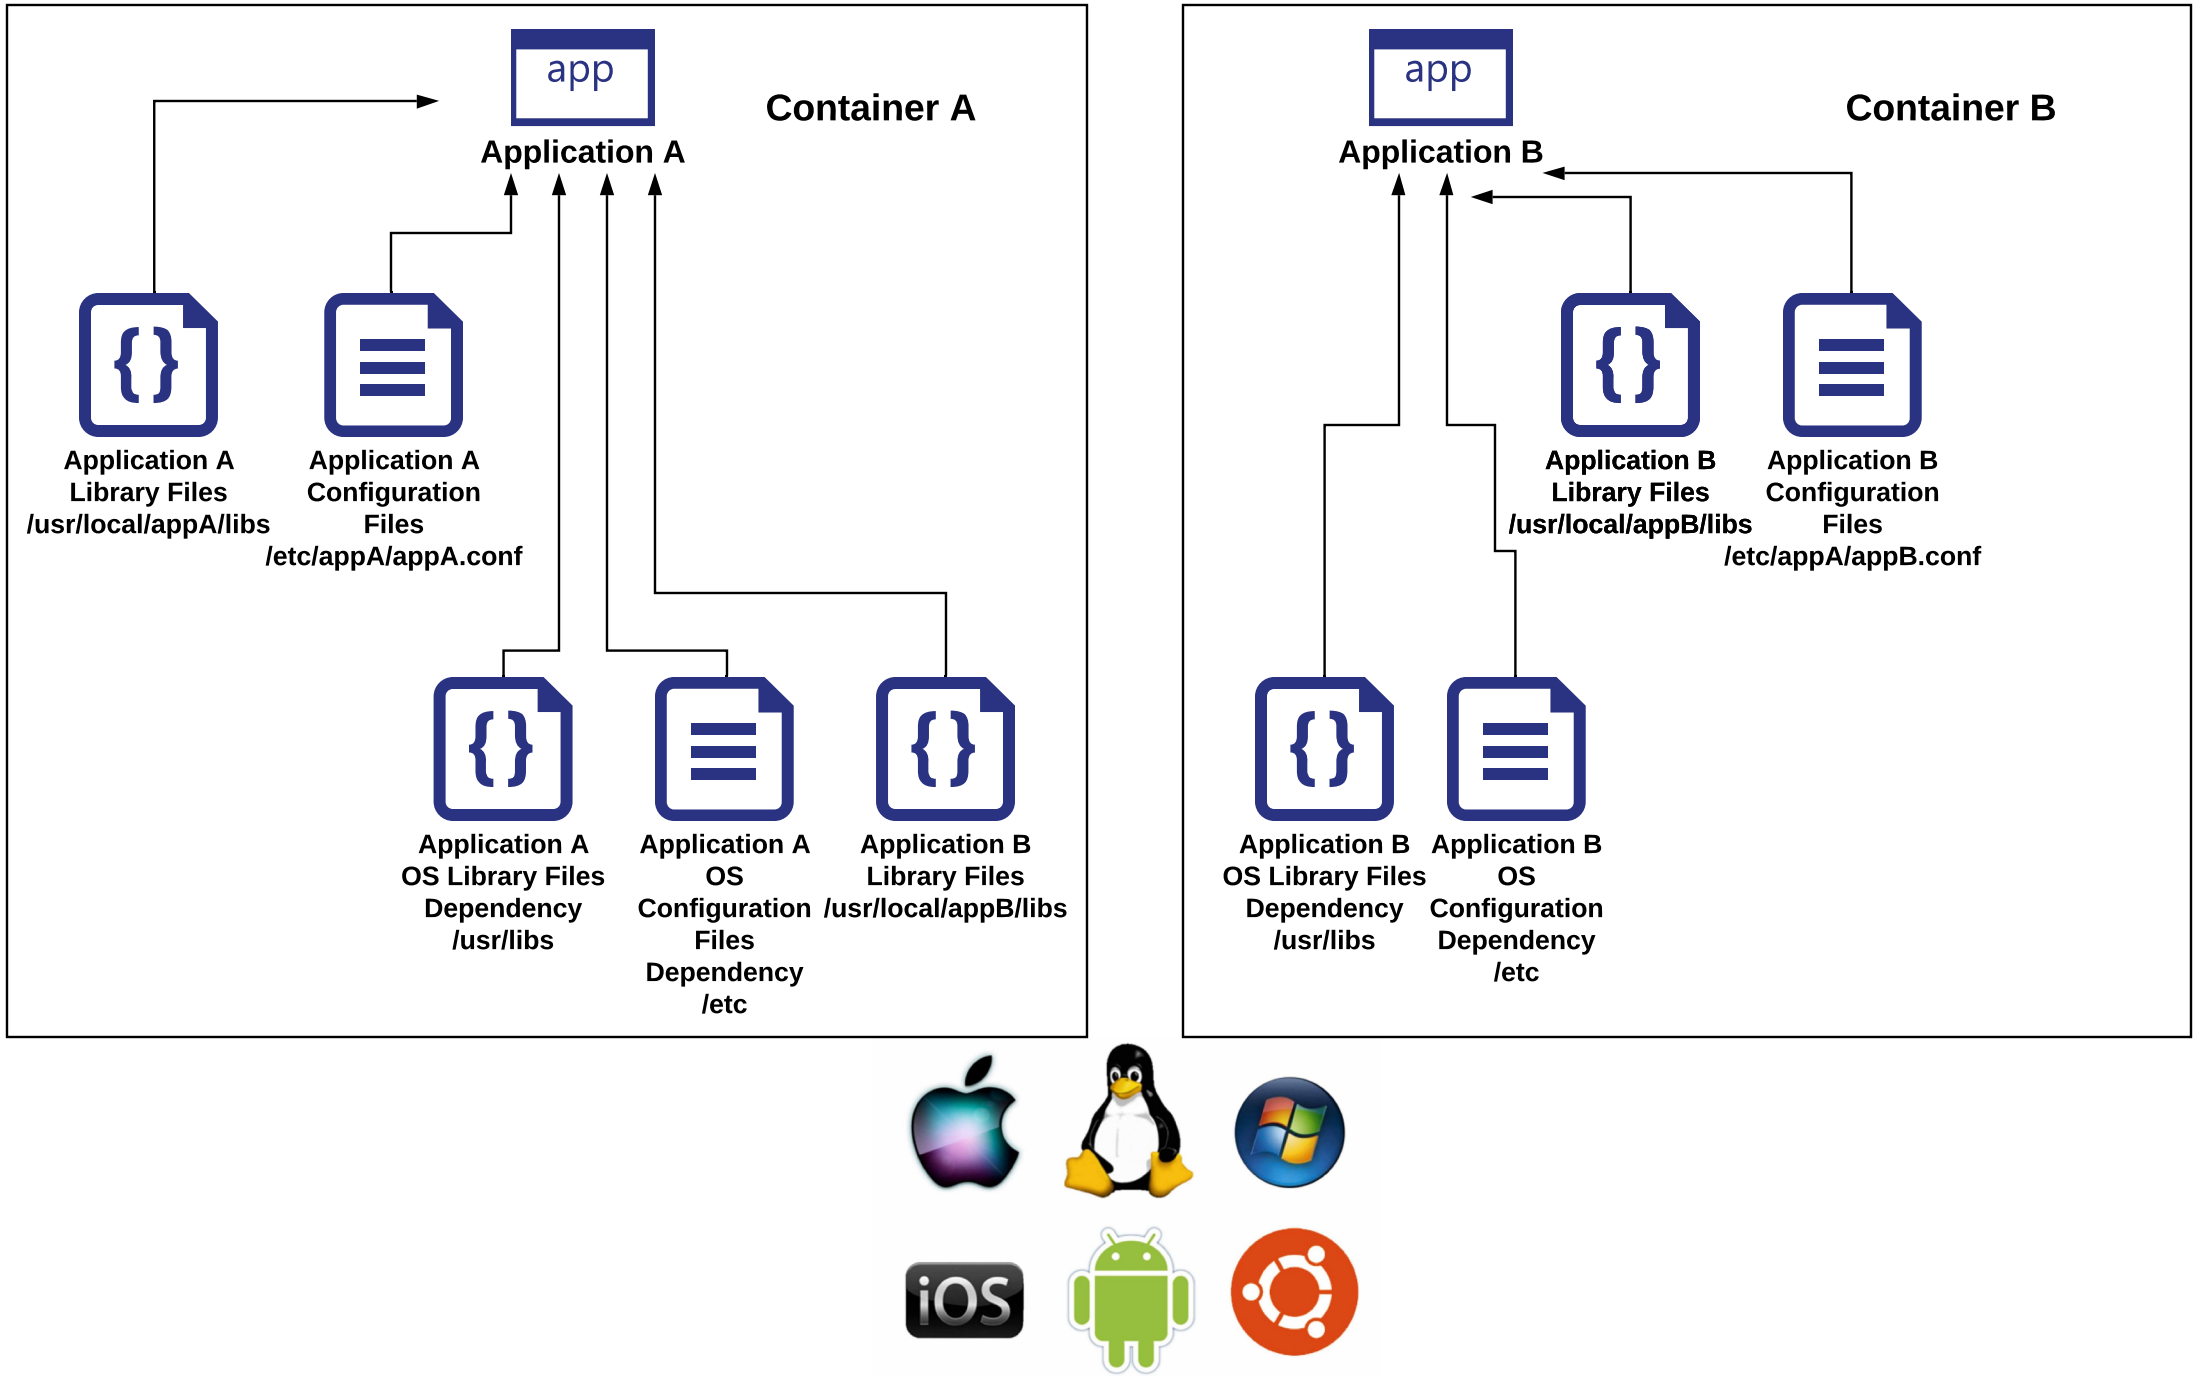
Traditional OS vs Container: Files Dependencies



Traditional OS vs Container: Files Dependencies



Comparison of Deploying Traditional App vs Stand Alone Containerized App vs Clustered Containerized App with Kubernetes/OpenShift

Traditional MariaDB Deployment

Install MariaDB Software Packages

```
yum group install mariadb mariadb-client
```

Main packages:
MySQL-python.x86_64 0:1.2.5-1.el7
mariadb.x86_64 1:5.5.64-1.el7
mariadb-server.x86_64 1:5.5.64-1.el7
mysql-connector-odbc.x86_64 0:5.2.5-8.el7

Dependency Packages:
perl-DBD-MySQL.x86_64 0:4.023-6.el7
unixODBC.x86_64 0:2.3.1-14.el7

Enable and Start MariaDB Service

```
systemctl enable mariadb
systemctl start mariadb
systemctl status mariadb
```

Create Database and User in MariaDB for WordPress

```
mysql -u root -p
SQL> CREATE DATABASE wordpress;
SQL> CREATE USER wordpress@localhost IDENTIFIED BY 'redhat';
SQL> GRANT ALL PRIVILEGES ON wordpress.* TO wordpress@localhost IDENTIFIED BY 'redhat';
SQL> FLUSH PRIVILEGES;
```

Use Physical Networking ⟷ **Use Virtual Network (Software Defined Network)**

Storage is always *persistent* ⟷ **Default storage is *ephemeral***

Stand Alone Containerized MariaDB

Pull MariaDB Image

```
docker image pull mariadb
docker image ls
```

Run MariaDB Container

```
docker container run -d --name wordpressdb \
-e MYSQL_ROOT_PASSWORD='redhat' \
-e MYSQL_DATABASE='wordpress' \
-e MYSQL_USER='wordpress' \
-e MYSQL_PASSWORD='redhat' \
-v /root/var/lib/mysql:/var/lib/mysql \
--network mariadb-wp-privnet \
-p 3306:3306
mariadb
```

Use Virtual Network (Software Defined Network)

```
docker network create --attachable mariadb-wp-privnetc
```

Create Persistent Storage/Volume

```
mkdir /root/var/lib/mysql
mount /dev/sdd
/root/var/lib/mysql
```

Clustered Containerized MariaDB with Kubernetes/OpenShift

Deploy Containerized MariaDB in Kubernetes

```
kubectl apply -f mariadb-deployment.yaml
```

Deploy Containerized MariaDB in OpenShift

```
oc create -f mariadb-deployment.yaml
```

Run as 3 containers on different worker servers

Image Name

The `mariadb-deployment.yaml` File

```

```

Deploying WordPress as Traditional Application on Non-clustered Environment

1. Install and Update CentOS 7

Download the ISO file of latest CentOS from available mirror site then install it on Virtual Host or Physical host. After finishing the install, update the Centos 7 software using the following command:

```
# yum clean all
# yum repolist
# yum update
```

For **reducing complexity,** in this tutorial I use the following scenario:

- login as root to run all command
- change **SELinux** setting to *permissive*
- *disable* **Dynamic Firewall**

Use the following command to change SELinux settings and disable Dynamic Firewall:

```
# setenforce 0
# getenforce
# sestatus
# vi /etc/selinux/config
  SELINUX=permissive
# systemctl disable firewalld
# systemctl stop firewalld
```

2. Install and Configure Apache Web Server with PHP Support

Use the following command to install Apache Web Server (*httpd*) and PHP:

```
# yum group list -v hidden |grep -i web
…
Maybe run: yum groups mark convert (see man yum)
   Basic Web Server (web-server-environment)
   Perl for Web (perl-web)
   Python (python-web)
   Web Server (web-server)
   Web Servlet Engine (web-servlet)

# yum group install web-server
…
Installed:
  crypto-utils.x86_64 0:2.4.1-42.el7                    httpd.x86_64 0:2.4.6-90.el7.centos
  httpd-manual.noarch 0:2.4.6-90.el7.centos             mod_fcgid.x86_64 0:2.3.9-6.el7
  mod_ssl.x86_64 1:2.4.6-90.el7.centos

Dependency Installed:
apr.x86_64 0:1.4.8-5.el7         apr-util.x86_64 0:1.5.2-6.el7    httpd-tools.x86_64 0:2.4.6-90.el7.centos
mailcap.noarch 0:2.1.41-2.el7    perl-Newt.x86_64 0:1.08-36.el7

Complete!

# yum group install php
…
Installed:
php.x86_64 0:5.4.16-46.1.el7_7     php-gd.x86_64 0:5.4.16-46.1.el7_7      php-pdo.x86_64 0:5.4.16-46.1.el7_7
php-pear.noarch 1:1.9.4-21.el7     php-xml.x86_64 0:5.4.16-46.1.el7_7
```

```
Dependency Installed:
libzip.x86_64 0:0.10.1-8.el7            php-cli.x86_64 0:5.4.16-46.1.el7_7      php-common.x86_64 0:5.4.16-46.1.el7_7
php-process.x86_64 0:5.4.16-46.1.el7_7  t1lib.x86_64 0:5.1.2-14.el7

Complete!

# yum install php-mysql
…
Installed:
  php-mysql.x86_64 0:5.4.16-46.1.el7_7

Complete!
```

3. Install MariaDB

Use the following command to install MariaDB Database software:

```
# yum group list -v hidden|grep -i maria
…
   MariaDB Database Client (mariadb-client)
  MariaDB Database Server (mariadb)

# yum group install mariadb mariadb-client
…
Installed:
  MySQL-python.x86_64 0:1.2.5-1.el7     mariadb.x86_64 1:5.5.64-1.el7    mariadb-server.x86_64 1:5.5.64-1.el7
  mysql-connector-odbc.x86_64 0:5.2.5-8.el7

Dependency Installed:
  perl-DBD-MySQL.x86_64 0:4.023-6.el7           unixODBC.x86_64 0:2.3.1-14.el7

Complete!
```

4. Enable, Start and Test Apache Web Functionality

Use the following command to enable and start Apache service:

```
# rpm -qa|grep httpd
# rpm -ql httpd|grep systemd
/etc/httpd/conf.modules.d/00-systemd.conf
/usr/lib/systemd/system/htcacheclean.service
/usr/lib/systemd/system/httpd.service
/usr/lib64/httpd/modules/mod_systemd.so

# systemctl status httpd
● httpd.service - The Apache HTTP Server
   Loaded: loaded (/usr/lib/systemd/system/httpd.service; disabled; vendor preset: disabled)
   Active: inactive (dead)
     Docs: man:httpd(8)
           man:apachectl(8)

# systemctl status htcacheclean
● htcacheclean.service - Disk Cache Cleaning Daemon for Apache HTTP Server
   Loaded: loaded (/usr/lib/systemd/system/htcacheclean.service; static; vendor preset:
disabled)
   Active: inactive (dead)
     Docs: man:htcacheclean(8)

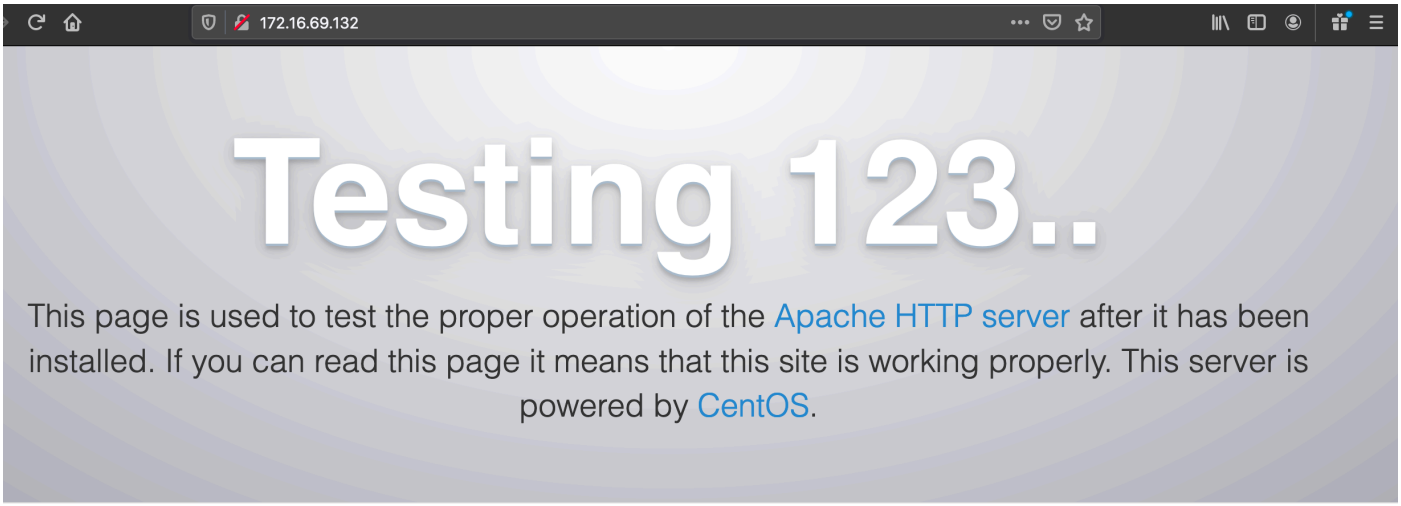
# systemctl enable httpd
Created symlink from /etc/systemd/system/multi-user.target.wants/httpd.service to
/usr/lib/systemd/system/httpd.service.
```

```
# systemctl start httpd

# systemctl status httpd
● httpd.service - The Apache HTTP Server
   Loaded: loaded (/usr/lib/systemd/system/httpd.service; enabled; vendor preset: disabled)
   Active: active (running) since Mon 2020-04-06 08:44:48 WIB; 4s ago
     Docs: man:httpd(8)
           man:apachectl(8)
 Main PID: 3909 (httpd)
   Status: "Processing requests..."
    Tasks: 7
   CGroup: /system.slice/httpd.service
           ├─3909 /usr/sbin/httpd -DFOREGROUND
           ├─3910 /usr/sbin/httpd -DFOREGROUND
           ├─3912 /usr/sbin/httpd -DFOREGROUND
           ├─3913 /usr/sbin/httpd -DFOREGROUND
           ├─3914 /usr/sbin/httpd -DFOREGROUND
           ├─3915 /usr/sbin/httpd -DFOREGROUND
           └─3916 /usr/sbin/httpd -DFOREGROUND

Apr 06 08:44:41 myserver1.mydomain.com systemd[1]: Starting The Apache HTTP Server...
Apr 06 08:44:47 myserver1.mydomain.com httpd[3909]: AH00558: httpd: Could not reliably
determine the server'...sage
Apr 06 08:44:48 myserver1.mydomain.com systemd[1]: Started The Apache HTTP Server.
Hint: Some lines were ellipsized, use -l to show in full.
```

Use web browser or *curl* to test access to the web server:



```
$ curl http://localhost|grep -i test
  …
            <title>Apache HTTP Server Test Page powered by CentOS</title>
        <h1>Testing 123..</h1>
            <p class="lead">This page is used to test the proper operation of the <a
href="http://apache.org">Apache HTTP server</a> after it has been installed. If you can read
this page it means that this site is working properly. This server is powered by <a
href="http://centos.org">CentOS</a>.</p>
```

5. Enable, Start and Test PHP Functionality

PHP packages **do not have service** to start. The following command show the content of main PHP package:

```
# rpm -qa|grep php
php-5.4.16-46.1.el7_7.x86_64
…
# rpm -ql php
/etc/httpd/conf.d/php.conf
/etc/httpd/conf.modules.d/10-php.conf
/usr/lib64/httpd/modules/libphp5.so
/usr/share/httpd/icons/php.gif
/var/lib/php/session
```

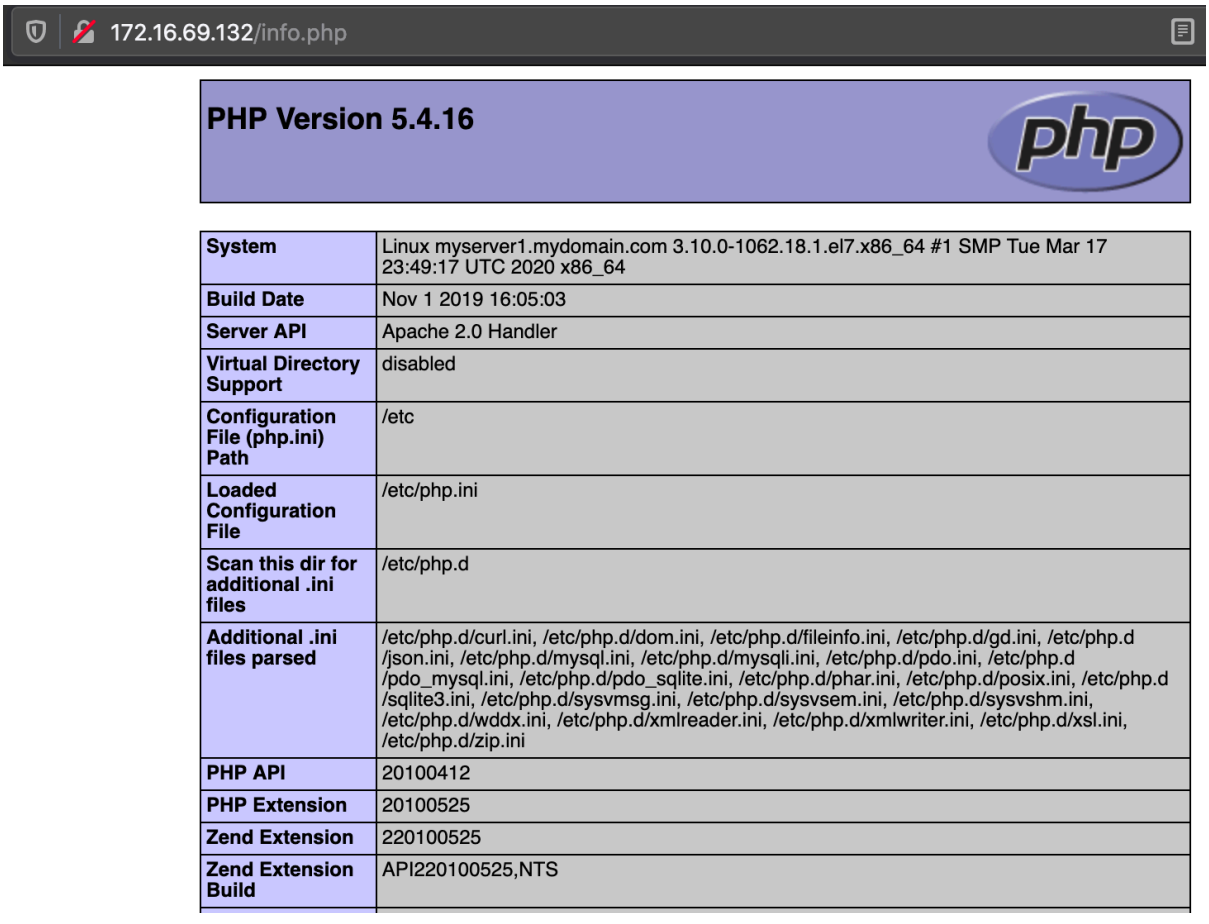
Create the following PHP script and use web browser or curl to run that script:

```
# cd /var/www/html

# vi info.php
<?php phpinfo(); ?>

$ curl http://localhost/info.php|grep -i version
…
<a href="http://www.php.net/"><img border="0" src="/info.php?=PHPE9568F34-D428-11d2-A769-
00AA001ACF42" alt="PHP Logo" /></a><h1 class="p">PHP Version 5.4.16</h1>
<tr><td class="e">Apache Version </td><td class="v">Apache/2.4.6 (CentOS) OpenSSL/1.0.2k-fips
mod_fcgid/2.3.9 PHP/5.4.16 </td></tr>
…
```

Here is the output from the web browser:



System	Linux myserver1.mydomain.com 3.10.0-1062.18.1.el7.x86_64 #1 SMP Tue Mar 17 23:49:17 UTC 2020 x86_64
Build Date	Nov 1 2019 16:05:03
Server API	Apache 2.0 Handler
Virtual Directory Support	disabled
Configuration File (php.ini) Path	/etc
Loaded Configuration File	/etc/php.ini
Scan this dir for additional .ini files	/etc/php.d

6. Enable, Start and Configure MariaDB Service

Use the following command to enable, start and configure MariaDB service:

```
# rpm -qa|grep mariadb
mariadb-5.5.64-1.el7.x86_64
mariadb-libs-5.5.64-1.el7.x86_64
mariadb-server-5.5.64-1.el7.x86_64

# rpm -ql mariadb-server|grep systemd
/usr/lib/systemd/system/mariadb.service

# systemctl status mariadb
● mariadb.service - MariaDB database server
   Loaded: loaded (/usr/lib/systemd/system/mariadb.service; disabled; vendor preset: disabled)
   Active: inactive (dead)

# systemctl enable mariadb
Created symlink from /etc/systemd/system/multi-user.target.wants/mariadb.service to
/usr/lib/systemd/system/mariadb.service.

# systemctl start mariadb

# systemctl status mariadb
● mariadb.service - MariaDB database server
   Loaded: loaded (/usr/lib/systemd/system/mariadb.service; enabled; vendor preset: disabled)
   Active: active (running) since Mon 2020-04-06 09:23:27 WIB; 5s ago

# mysql_secure_installation

NOTE: RUNNING ALL PARTS OF THIS SCRIPT IS RECOMMENDED FOR ALL MariaDB
      SERVERS IN PRODUCTION USE!  PLEASE READ EACH STEP CAREFULLY!

In order to log into MariaDB to secure it, we'll need the current
```

```
password for the root user.  If you've just installed MariaDB, and
you haven't set the root password yet, the password will be blank,
so you should just press enter here.

Enter current password for root (enter for none):
OK, successfully used password, moving on...

Setting the root password ensures that nobody can log into the MariaDB
root user without the proper authorisation.

Set root password? [Y/n] y
New password:
Re-enter new password:
Password updated successfully!
Reloading privilege tables..
 ... Success!

By default, a MariaDB installation has an anonymous user, allowing anyone
to log into MariaDB without having to have a user account created for
them.  This is intended only for testing, and to make the installation
go a bit smoother.  You should remove them before moving into a
production environment.

Remove anonymous users? [Y/n] y
 ... Success!

Normally, root should only be allowed to connect from 'localhost'.  This
ensures that someone cannot guess at the root password from the network.

Disallow root login remotely? [Y/n] y
 ... Success!

By default, MariaDB comes with a database named 'test' that anyone can
access.  This is also intended only for testing, and should be removed
before moving into a production environment.

Remove test database and access to it? [Y/n] y
 - Dropping test database...
 ... Success!
 - Removing privileges on test database...
 ... Success!

Reloading the privilege tables will ensure that all changes made so far
will take effect immediately.

Reload privilege tables now? [Y/n] y
 ... Success!

Cleaning up...

All done!  If you've completed all of the above steps, your MariaDB
installation should now be secure.

Thanks for using MariaDB!
```

7. Create Database and User in MariaDB for WordPress

Use the following command to create database and user in MariaDB to be accessed by WordPress:

```
# mysql -u root -p
Enter password:
…
MariaDB [(none)]> create database wordpress;
Query OK, 1 row affected (0.01 sec)
MariaDB [(none)]> create user wordpress@localhost identified by 'redhat';
Query OK, 0 rows affected (0.01 sec)
MariaDB [(none)]> grant all privileges on wordpress.* to wordpress@localhost identified by
'redhat';
Query OK, 0 rows affected (0.00 sec)
MariaDB [(none)]> flush privileges;
Query OK, 0 rows affected (0.00 sec)
MariaDB [(none)]> exit
Bye
```

8. Download, Install and Create Initial Configuration of WordPress

Make sure you know your PHP version, use the following command:

```
# php -v
PHP 5.4.16 (cli) (built: Nov  1 2019 16:04:20)
Copyright (c) 1997-2013 The PHP Group
Zend Engine v2.4.0, Copyright (c) 1998-2013 Zend Technologies
```

The compatibility of **PHP 5.4** version is **WordPress 5.0** version**.** Use graphical browser, *wget* or *curl* to download the WordPress software on the following URL:

5.0 Branch

5.0.8	December 12, 2019	zip (md5 | sha1)	tar.gz (md5 | sha1)	IIS zip (md5 | sha1)
5.0.7	October 14, 2019	zip (md5 | sha1)	tar.gz (md5 | sha1)	IIS zip (md5 | sha1)
5.0.6	September 5, 2019	zip (md5 | sha1)	tar.gz (md5 | sha1)	IIS zip (md5 | sha1)
5.0.4	March 13, 2019	zip (md5 | sha1)	tar.gz (md5 | sha1)	IIS zip (md5 | sha1)
5.0.3	January 9, 2019	zip (md5 | sha1)	tar.gz (md5 | sha1)	IIS zip (md5 | sha1)
5.0.2	December 19, 2018	zip (md5 | sha1)	tar.gz (md5 | sha1)	IIS zip (md5 | sha1)
5.0.1	December 13, 2018	zip (md5 | sha1)	tar.gz (md5 | sha1)	IIS zip (md5 | sha1)

The following commands demonstrate how to download, install and create initial configuration for WordPress:

```
# cd Downloads

# wget https://wordpress.org/wordpress-5.0.8.tar.gz

# ls
wordpress-5.0.8.tar.gz

# tar xzf wordpress-5.0.8.tar.gz

# ls -l
total 10276
drwxr-xr-x. 5 nobody nfsnobody     4096 Dec 13 04:36 wordpress
-rw-r--r--. 1 root   root      10516757 Apr 12 08:34 wordpress-5.0.8.tar.gz

# cp -a wordpress /var/www/html

# cd /var/www/html/wordpress

# mkdir wp-content/uploads

# cp wp-config-sample.php wp-config.php

# vi wp-config.php
…
// ** MySQL settings - You can get this info from your web host ** //
/** The name of the database for WordPress */
define( 'DB_NAME', 'wordpress' );

/** MySQL database username */
define( 'DB_USER', 'wordpress' );

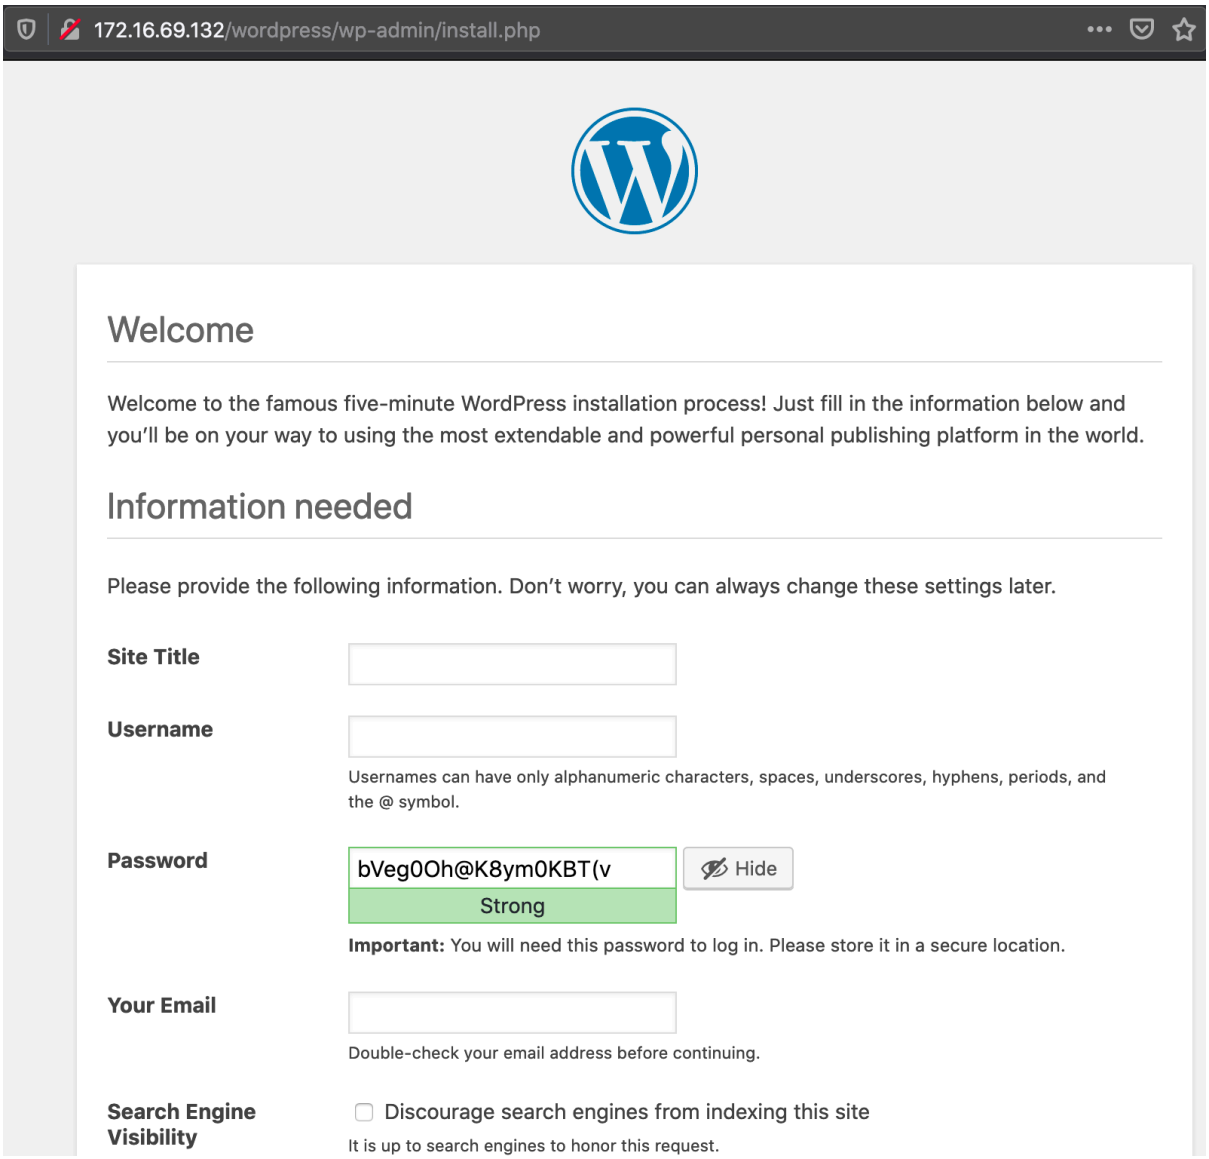
/** MySQL database password */
define( 'DB_PASSWORD', 'redhat' );

/** MySQL hostname */
define( 'DB_HOST', 'localhost' );
…

# cd ..
# chown -R apache:apache wordpress
```

9. Access WordPress for Creating Additional Configuration

Now, WordPress application is ready on the following URL: http://hostname/wordpress for creating additional configuration.



That's all, thank you.

Deploying WordPress as Docker Containerized Application on Non-clustered Environment

1. Install and Update CentOS 7

Download an ISO file of the latest CentOS from available mirror sites then install it on Virtual Host or Physical host. After finishing the install, update the CentOS 7 software using the following command:

```
# yum clean all
# yum repolist
# yum update
```

For **reducing complexity** in this tutorial, I use the following scenario:

- Login as `root` to run all command
- Change **SELinux** setting to `permissive`

Use the following command to change SELinux settings and disable Dynamic Firewall:

```
# setenforce 0
# getenforce
# sestatus
# vi /etc/selinux/config
  SELINUX=permissive
```

2. Install Docker Software and Start Docker Service

Use the following command to install Docker Desktop Community Edition from Docker Repository:

Index of linux/centos/

../
7/
docker-ce.repo 2019-10-18 21:57:38 2.4 KiB
gpg 2019-10-18 21:57:38 1.6 KiB

```
# wget https://download.docker.com/linux/centos/docker-ce.repo

# ls
docker-ce.repo

# cp docker-ce.repo /etc/yum.repos.d/

# yum repolist
…
docker-ce-stable                                          | 3.5 kB   00:00
(1/2): docker-ce-stable/x86_64/primary_db                 |  41 kB   00:00
(2/2): docker-ce-stable/x86_64/updateinfo                 |   55 B   00:00
```

```
repo id                              repo name                                status
base/7/x86_64                        CentOS-7 - Base                          10,097
docker-ce-stable/x86_64              Docker CE Stable - x86_64                    70
extras/7/x86_64                      CentOS-7 - Extras                           341
updates/7/x86_64                     CentOS-7 - Updates                        1,787
repolist: 12,295

# yum list|grep docker
…

# docker container run hello-world

Hello from Docker!
This message shows that your installation appears to be working correctly.

To generate this message, Docker took the following steps:
 1. The Docker client contacted the Docker daemon.
 2. The Docker daemon pulled the "hello-world" image from the Docker Hub.
    (amd64)
 3. The Docker daemon created a new container from that image which runs the
    executable that produces the output you are currently reading.
 4. The Docker daemon streamed that output to the Docker client, which sent it
    to your terminal.

To try something more ambitious, you can run an Ubuntu container with:
 $ docker run -it ubuntu bash

Share images, automate workflows, and more with a free Docker ID:
 https://hub.docker.com/

For more examples and ideas, visit:
 https://docs.docker.com/get-started/
```

4. Download MariaDB and WordPress Image from Docker Image Registry

Use the following commands to download MariaDB and WordPress Image from Docker Image Registry:

```
# docker search mariadb

hello-world                   latest              fce289e99eb9        15 months ago      1.84kB
```

5. Create Persistent Volume for MariaDB and WordPress

Use the following commands to create *persistent volume* for both MariaDB and WordPress:

```
# mkdir -p /root/var/lib/mysql

# mkdir -p /root/var/www/html

# ls -lR var
var:
total 0
drwxr-xr-x. 3 root root 19 Apr 13 06:38 lib
drwxr-xr-x. 3 root root 18 Apr 13 06:38 www

var/lib:
total 0
drwxr-xr-x. 2 root root 6 Apr 13 06:38 mysql

var/lib/mysql:
total 0

var/www:
total 0
drwxr-xr-x. 2 root root 6 Apr 13 06:38 html

var/www/html:
total 0
```

6. Create Virtual Private Network for WordPress and MariaDB Container

Use the following commands to create Docker *virtual private network*:

```
# docker network ls
NETWORK ID          NAME                DRIVER              SCOPE
ceb9d2e9cbad        bridge              bridge              local
9d3c1b497be8        host                host                local
9da389311d9e        none                null                local

# docker network create --attachable mariadb-wp-privnet
90f36038fcaf6c19c598d0a7a6ddcc902d0af6f59dd2cdfed1e1df2d35eff02e

# docker network ls
NETWORK ID          NAME                 DRIVER              SCOPE
ceb9d2e9cbad        bridge               bridge              local
9d3c1b497be8        host                 host                local
90f36038fcaf        mariadb-wp-privnet   bridge              local
9da389311d9e        none                 null                local
```

7. Run MariaDB and WordPress Container

For the purpose of running MariaDB and WordPress container, create the following shell scripts:

```
# vi run_mariadb_with_persistent_volume_and_private_network.sh
#!/bin/bash

docker container run -d \
--name wordpressdb \
-e MYSQL_ROOT_PASSWORD='redhat' \
-e MYSQL_DATABASE='wordpress' \
-e MYSQL_USER='wordpress' \
-e MYSQL_PASSWORD='redhat' \
-v /root/var/lib/mysql:/var/lib/mysql \
--network mariadb-wp-privnet \
mariadb

# vi run_wordpress_with_persistent_volume_and_published_port.sh
#!/bin/bash

docker container run -d \
--name wordpress \
-e WORDPRESS_DB_HOST=wordpressdb \
-e WORDPRESS_DB_USER='wordpress' \
-e WORDPRESS_DB_PASSWORD='redhat' \
-e WORDPRESS_DB_NAME='wordpress' \
-v /root/var/www/html:/var/www/html \
--network mariadb-wp-privnet  \
-p 80:80 \
wordpress

# chmod +x run_mariadb_with_persistent_volume_and_private_network.sh
# chmod +x run_wordpress_with_persistent_volume_and_published_port.sh

# ./run_mariadb_with_persistent_volume_and_private_network.sh
b596071feb0035fa3590860bc979a0769141a2de8b080235722ce0b2f1b3345c

# ./run_wordpress_with_persistent_volume_and_published_port.sh
10f0489842c8887aba174399af3cb308885ae32cdc3e0603638192f250eee48a

# docker container ls
CONTAINER ID   IMAGE       COMMAND                  CREATED         STATUS        PORTS                NAMES
10f0489842c8   wordpress   "docker-entrypoint.s…"    2 seconds ago  Up 2 seconds  0.0.0.0:80->80/tcp   wordpress
b596071feb00   mariadb     "docker-entrypoint.s…"  28 second ago   Up 28 seconds 3306/tcp             wordpressdb
```

8. Open HTTP Port in Dynamic Firewall and Access WordPress

Use the following command to open HTTP port in Dynamic Firewall:

```
# firewall-cmd --get-active-zones
public
  interfaces: ens33

# firewall-cmd --list-services
dhcpv6-client ssh

# firewall-cmd --permanent --add-service=http

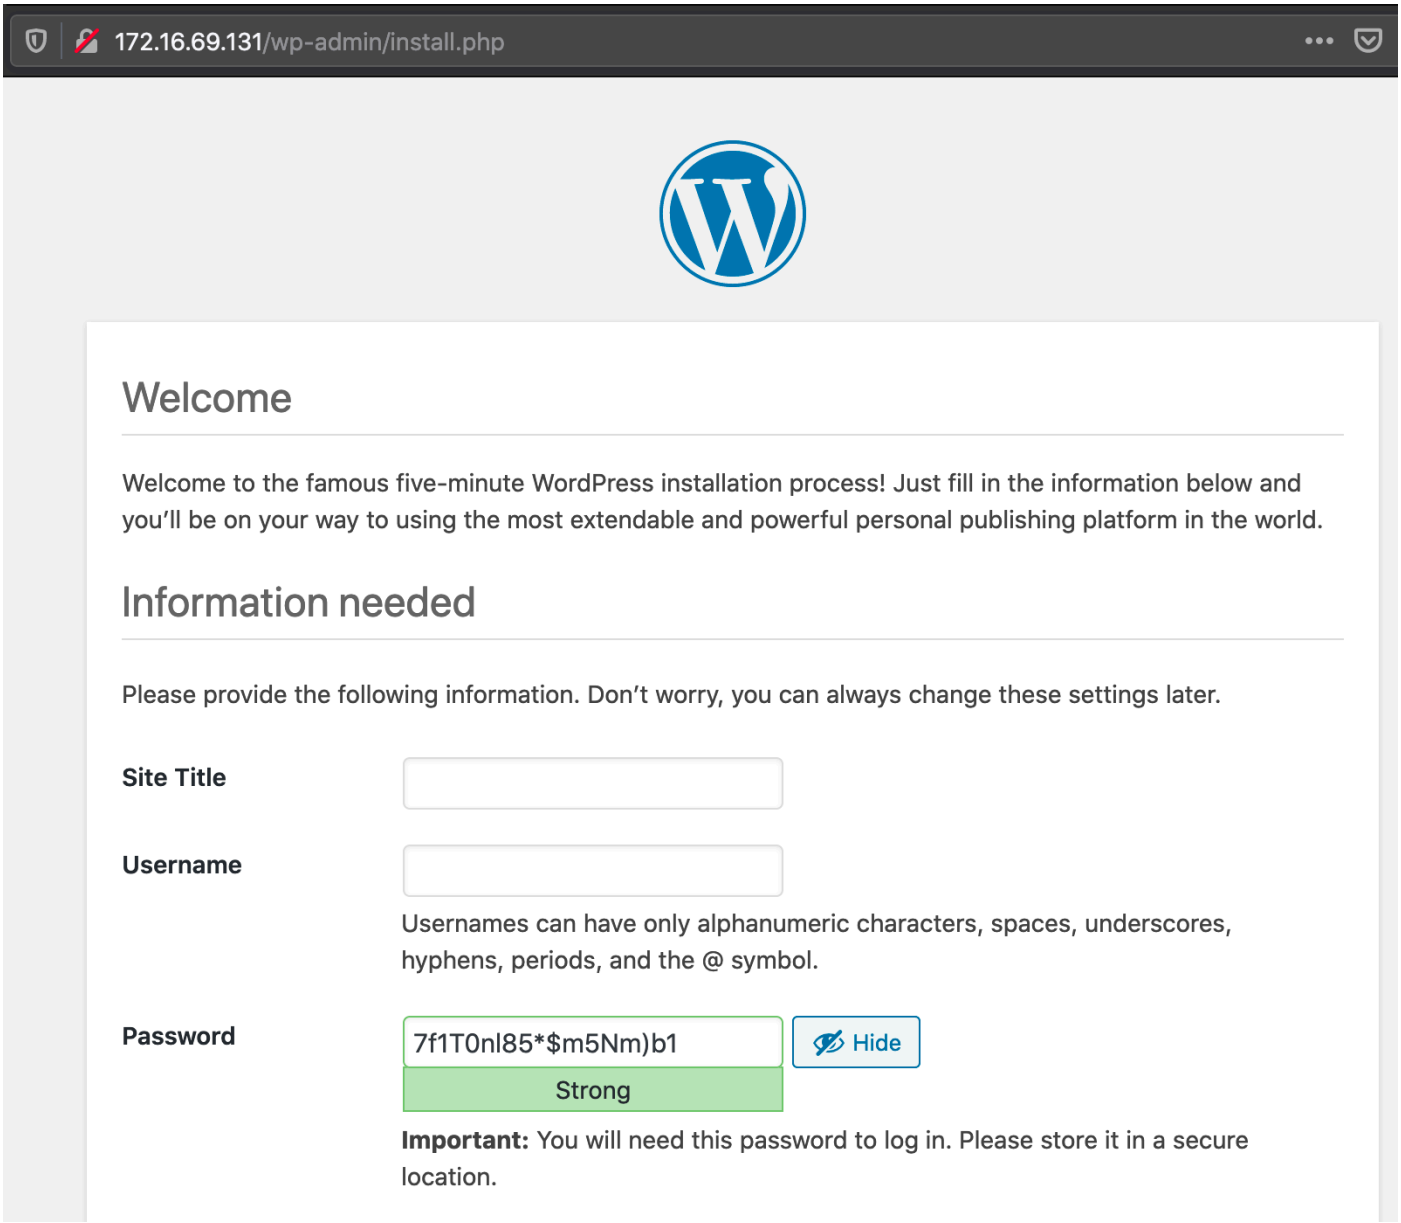
# firewall-cmd –reload

# firewall-cmd --list-services
dhcpv6-client http ssh
```

To perform simple accessibility testing of WordPress, from localhost run the following command:

```
# curl -L http://localhost|grep -i welcome
…
       <h1>Welcome</h1>
<p>Welcome to the famous five-minute WordPress installation process! Just fill in the
information below and you&#8217;ll be on your way to using the most extendable and powerful
personal publishing platform in the world.</p>
…
```

Finally access WordPress using graphical web browser:



That's all, thank you.

Deploying WordPress as Docker Containerized Application on Clustered Environment with Kubernetes

1. Install and Update CentOS 7

Download an ISO file of the latest CentOS from available mirror sites then install it on Virtual Host or Physical host. After finishing the install, update the CentOS 7 software using the following command:

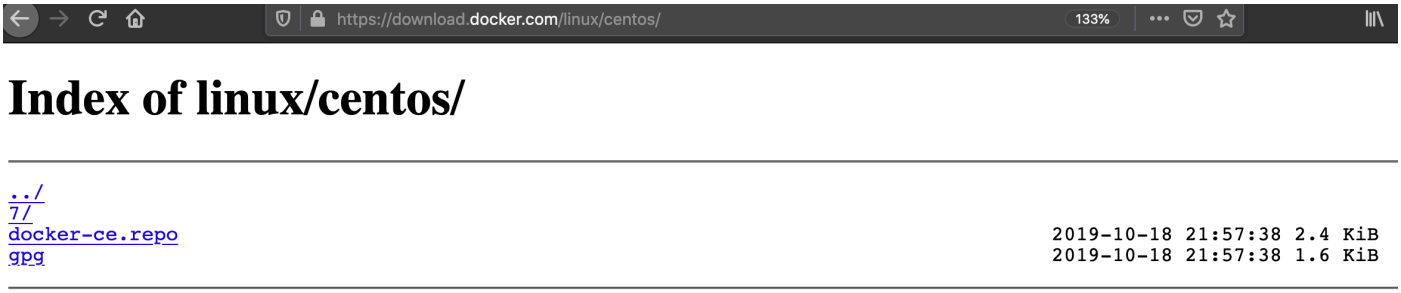
```
# yum clean all
# yum repolist
# yum update
```

For **reducing complexity** in this tutorial, set SELinux setting to `permissive`. Use the following command to change SELinux settings:

```
# setenforce 0
# getenforce
# sestatus
# vi /etc/selinux/config
  SELINUX=permissive
```

2. Install Docker Software and Start Docker Service

Use the following command to install Docker Desktop Community Edition from Docker Repository:



```
# wget https://download.docker.com/linux/centos/docker-ce.repo

# ls
docker-ce.repo

# cp docker-ce.repo /etc/yum.repos.d/

# yum repolist
…
docker-ce-stable                                          | 3.5 kB   00:00
(1/2): docker-ce-stable/x86_64/primary_db                 |  41 kB   00:00
(2/2): docker-ce-stable/x86_64/updateinfo                 |   55 B   00:00
```

```
repo id                              repo name                              status
base/7/x86_64                        CentOS-7 - Base                        10,097

# docker container run hello-world

Hello from Docker!
This message shows that your installation appears to be working correctly.

To generate this message, Docker took the following steps:
 1. The Docker client contacted the Docker daemon.
 2. The Docker daemon pulled the "hello-world" image from the Docker Hub.
    (amd64)
 3. The Docker daemon created a new container from that image which runs the
    executable that produces the output you are currently reading.
 4. The Docker daemon streamed that output to the Docker client, which sent it
    to your terminal.

To try something more ambitious, you can run an Ubuntu container with:
 $ docker run -it ubuntu bash

Share images, automate workflows, and more with a free Docker ID:
 https://hub.docker.com/

For more examples and ideas, visit:
 https://docs.docker.com/get-started/
```

4. Download and Install ***kubectl*** Program

Use the following command to check the current version of `kubectl` is available at Google API site:

```
# curl https://storage.googleapis.com/kubernetes-release/release/stable.txt
v1.18.1
```

Use the following command to download and install `kubectl`:

```
# cd Downloads
# wget https://storage.googleapis.com/kubernetes-release/release/v1.18.1/bin/linux/amd64/kubectl
…
Connecting to storage.googleapis.com (storage.googleapis.com)|172.253.118.128|:443...
connected.
```

```

# cp minikube /usr/local/bin

# minikube version
minikube version: v1.9.2
commit: 93af9c1e43cab9618e301bc9fa720c63d5efa393
```

6. Create Regular User with Membership of **docker** Group

Use the following command to create user with membership of docker group:

```
# useradd -G docker kube

# id kube
uid=1001(kube) gid=1001(kube) groups=1001(kube),982(docker)

# su - kube

$ id
uid=1001(kube) gid=1001(kube) groups=1001(kube),982(docker)
context=unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023

$ docker search hello
NAME                                      DESCRIPTION
STARS               OFFICIAL            AUTOMATED
hello-world                               Hello World! (an example of minimal Dockeriz…   1163
[OK]
```

7. Configure Single Node Kubernetes Cluster with ***minikube***

The following command will create *single node Kubernetes cluster that run as docker container*:

```
$ minikube config set driver docker
❗  These changes will take effect upon a minikube delete and then a minikube start

$ minikube start --driver=docker
😄  minikube v1.9.2 on Centos 7.7.1908
✨  Using the docker driver based on user configuration

🌟  Enabling addons: default-storageclass, storage-provisioner
🏄  Done! kubectl is now configured to use "minikube"
```

8. Explore **minikube** Kubernetes Cluster Environment

The following commands show basic information of minikube Kubernetes cluster:

```
$ docker image ls
REPOSITORY                      TAG                 IMAGE ID            CREATED             SIZE
…
gcr.io/k8s-minikube/kicbase     v0.0.8              11589cdc9ef4        2 weeks ago         964MB

$ docker container ls
CONTAINER ID        IMAGE                                  COMMAND                  CREATED
STATUS              PORTS
NAMES

```

9. Deploy MariaDB and WordPress on Kubernetes Cluster

Use the following command to create the persistent volume directory for MariaDB and WordPress:

```
$ pwd
/home/kube

$ mkdir wordpressdb-data

$ sudo chown polkitd:root wordpressdb-data

$ mkdir wordpress-data

$ sudo chown 33:tape wordpress-data
```

Create the necessary YAML files for deploying MariaDB:

```
$ mkdir wordpress-config

$ cd wordpress-config

$ vi wordpressdb-pv-pvc.yaml
apiVersion: v1
kind: PersistentVolume
metadata:
  name: wordpressdb-pv
  labels:
    type: local
spec:
  storageClassName: manual
  capacity:
    storage: 20Gi
  accessModes:
    - ReadWriteOnce
  hostPath:
    path: "/home/kube/wordpressdb-data"
---
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
```

```
  name: wordpressdb-pvc
  labels:
    app: wordpress
spec:
  storageClassName: manual
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 20Gi

$ vi wordpressdb-svc.yaml
apiVersion: v1
kind: Service
metadata:
  name: wordpressdb-svc
  labels:
    app: wordpress
spec:
  ports:
  - port: 3306
    protocol: TCP
    targetPort: 3306
  selector:
    app: wordpress
    tier: wordpressdb
  type: ClusterIP
  clusterIP: None

$ vi wordpressdb-deployment.yaml
---
apiVersion: apps/v1 # for versions before 1.9.0 use apps/v1beta2
kind: Deployment
metadata:
  name: wordpressdb-deploy
  labels:
    app: wordpress
spec:
  selector:
    matchLabels:
      app: wordpress
      tier: wordpressdb
  strategy:
    type: Recreate
  template:
    metadata:
      labels:
        app: wordpress
        tier: wordpressdb
    spec:
      containers:
      - image: mariadb:10.5.2-bionic
        name: wordpressdb-container
        env:
          # Use secret in real usage
        - name: MYSQL_ROOT_PASSWORD
          value: redhat
        - name: MYSQL_USER
          value: wordpress
        - name: MYSQL_PASSWORD
          value: redhat
        - name: MYSQL_DATABASE
          value: wordpress
        ports:
        - containerPort: 3306
```

```
          name: wordpressdb-svc
        volumeMounts:
        - name: wordpressdb-persistent-storage
          mountPath: /var/lib/mysql
      volumes:
      - name: wordpressdb-persistent-storage
        persistentVolumeClaim:
          claimName: wordpressdb-pvc
```

Create the necessary YAML files for deploying WordPress:

```
$ vi wordpress-pv-pvc.yaml
apiVersion: v1
kind: PersistentVolume
metadata:
  name: wordpress-pv
  labels:
    type: local
spec:
  storageClassName: manual
  capacity:
    storage: 5Gi
  accessModes:
    - ReadWriteOnce
  hostPath:
    path: "/home/kube/wordpress-data"
---
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: wordpress-pvc
  labels:
    app: wordpress
spec:
  storageClassName: manual
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 5Gi

$ vi wordpress-svc.yaml
apiVersion: v1
kind: Service
metadata:
  name: wordpress-svc
  labels:
    app: wordpress
spec:
  ports:
    - port: 80
  selector:
    app: wordpress
    tier: frontend
  type: LoadBalancer

$ vi wordpress-deployment.yaml
---
apiVersion: apps/v1 # for versions before 1.9.0 use apps/v1beta2
kind: Deployment
metadata:
  name: wordpress-deploy
  labels:
```

```
    app: wordpress
spec:
  selector:
    matchLabels:
      app: wordpress
      tier: frontend
  strategy:
    type: Recreate
  template:
    metadata:
      labels:
        app: wordpress
        tier: frontend
    spec:
      containers:
      - image: wordpress:5.4.0-php7.2-apache
        name: wordpress
        env:
        - name: WORDPRESS_DB_HOST
          value: wordpressdb-svc
        - name: WORDPRESS_DB_PASSWORD
          value: redhat
        - name: WORDPRESS_DB_USER
          value: wordpress
        - name: WORDPRESS_DB_NAME
          value: wordpress
        ports:
        - containerPort: 80
          name: wordpress-svc
        volumeMounts:
        - name: wordpress-persistent-storage
          mountPath: /var/www/html
      volumes:
      - name: wordpress-persistent-storage
        persistentVolumeClaim:
          claimName: wordpress-pvc
```

Create `kustomization.yaml` File:

```
$ vi kustomization.yaml
resources:
- wordpressdb-pv-pvc.yaml
- wordpressdb-svc.yaml
- wordpressdb-deployment.yaml
- wordpress-pv-pvc.yaml
- wordpress-svc.yaml
- wordpress-deployment.yaml
```

Start deploying MariaDB and WordPress Using the following command:

```
$ pwd
/home/kube/wordpress-config

$ kubectl apply -k ./
```
